Summary of seafloor geodetic Survey in Taiwan

- 3 transponders were installed at three sites.
- 2-4 times were surveyed at each site.
- Noise levels were high, mainly originated from ships
- Numbers of acoustic shots used are not sufficient.
- At the Ilan site, the location accuracy is highest about 10 cm.

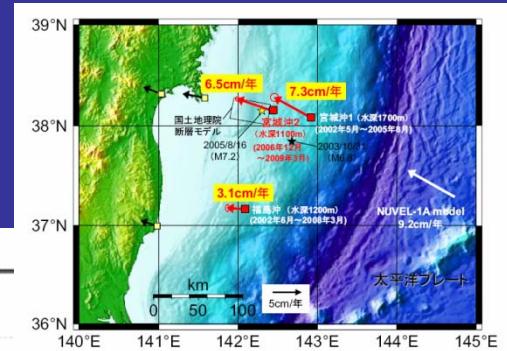

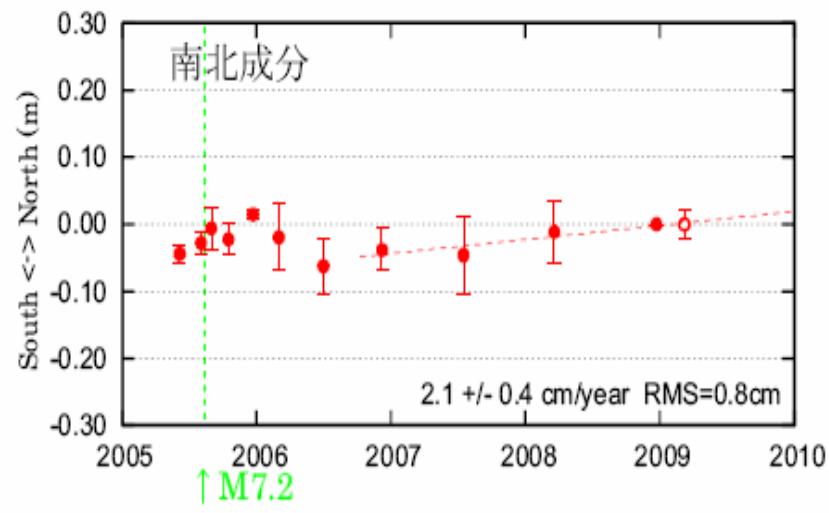

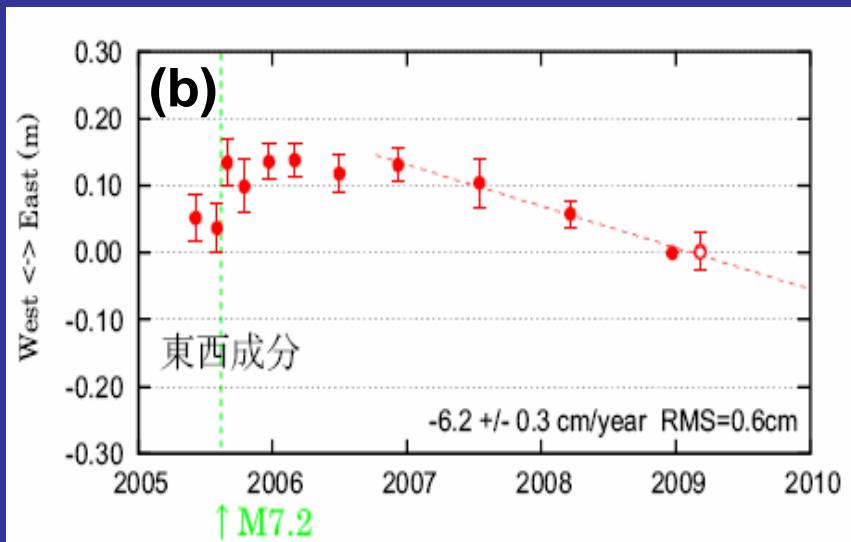

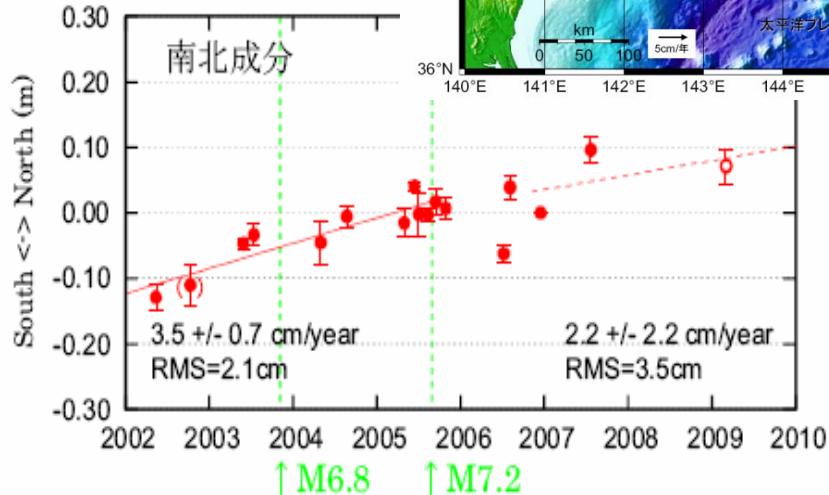

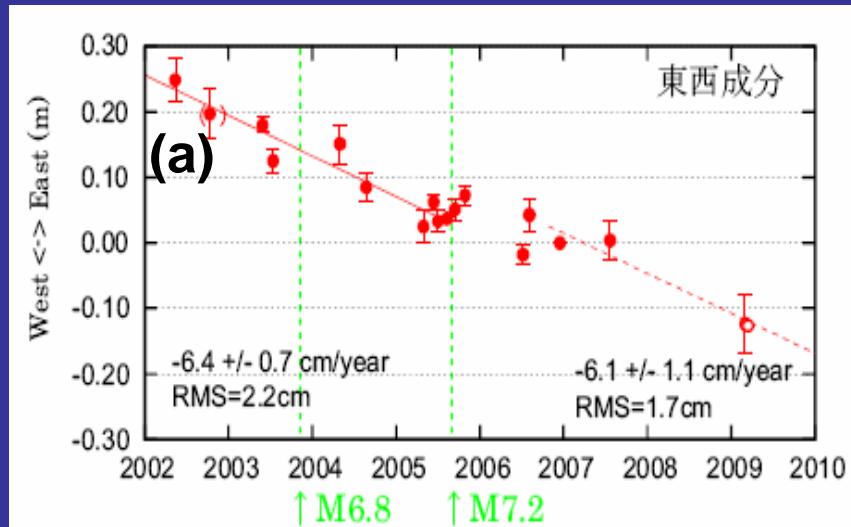

Comparison of the four groups

| | No. of sites | transponders/site | Accuracy single trend in cm | Vessel | TD attach | No. of shots/transponder | AC data picking |
|--------------|--------------|-------------------|-----------------------------|-----------------------------|-------------------|--------------------------|-----------------|
| Taiwan | 3 | 3 | 10-20cm ? | different even at same site | buoy or ship side | 400-1500 | manual |
| Coast Guard | 16 | 4 | 2-3cm 1-2cm | same at all sites | ship bottom | 1300 | auto |
| Nagoya Univ. | 7 | 3 | 5cm 3cm | same at same site | ship side | 1000-2000 | auto |
| Ryukyu Univ. | 1 | 3 | 5cm 5cm | same | ship side | 700-2000 | manual |

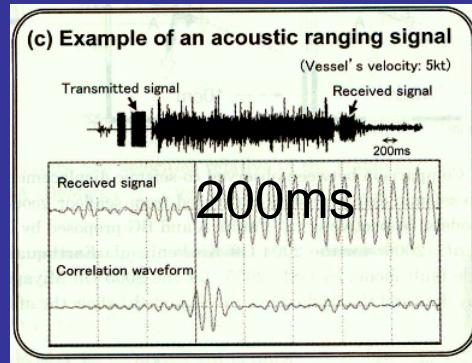

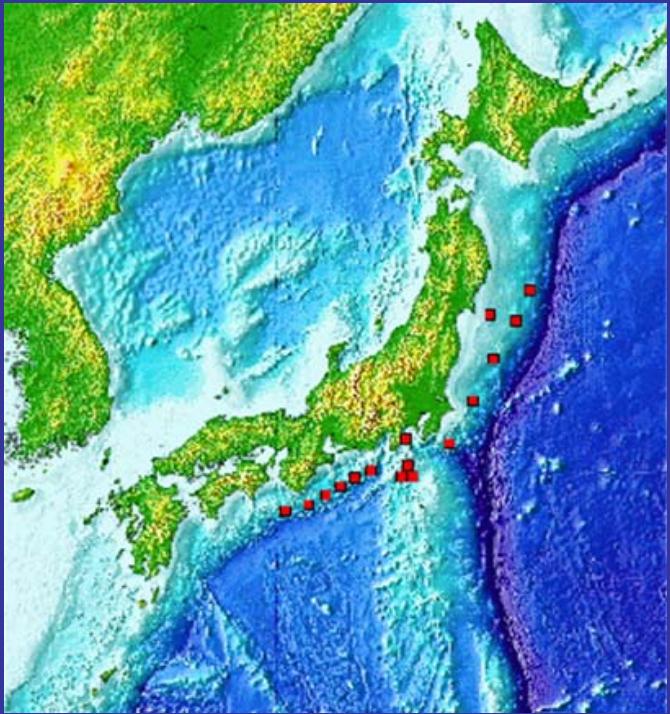

Accuracy of the Seafloor Geodetic Observations performed by the Coast guard

Off Miyagi, Northern Honshu, 100% Coupling

Why has the Coast Guard of Japan obtained the high accuracy?

Taiwan

1. Systematic observation: one subset of 4 hours x 2 times x 6 sites x 2 (round trip) x 2 regions (north and west) x 3 seasons = 96 days/year
2. Ship-bottom transducer
3. Long duration of transmitting signals

Our future plan

- Another site will be installed south of Taiwan.
- More shots are necessary for each survey.
- Low noise-level conditions are required:
 - Use of low noise-level fishing boats
 - Produce of a new manageable buoy
- A ship-bottom transducer is favorable for effective and high-accuracy surveys.
- A new PC-base system should be established.
